backtest

Backtesting via Value-at-Risk (VaR)

## Description

Method for backtesting a model obtained from bekk\_fit in terms of VaR-forcasting accuracy using a rolling window approach.

## Usage

```
backtest(
    x,
    window_length = 1000,
    p = 0.99,
    portfolio_weights = NULL,
    n.ahead = 1,
    distribution = "empirical",
    nc = 1
)
```

## **Arguments**

| х               | An object of class "bekkFit" from the function bekk_fit.  |
|-----------------|---|
| window_length   | An integer specifying the length of the rolling window.   |
| p               | A numerical value that determines the confidence level. The default value is set at 0.99 in accordance with the Basel Regulation.   |
| portfolio_weigh | nts   |
|                 | A vector determining the portfolio weights to calculate the portfolio VaR. If set to "NULL", the univariate VaR for each series are calculated.   |
| n.ahead         | Number of periods to predict conditional volatility. Default is a one-period ahead forecast.  |
| distribution    | A character string determining the assumed distribution of the residuals. Implemented are "normal", "empirical" and "t". The default is assuming the empirical distribution of the residuals. |
| nc              | Number of cores to be used for parallel computation.  |

## Value

Returns a S3 class "backtest" object containing the VaR forecast, out-of-sample returns and backtest statistics according to the R-package "GAS". conf

BEKKs 3

#### **Examples**

```
data(StocksBonds)
obj_spec <- bekk_spec()
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
# backtesting
x2 <- backtest(x1, window_length = 6000, n.ahead = 1, nc = 1)
plot(x2)
# backtesting using 5 day-ahead forecasts
x3 <- backtest(x1, window_length = 6000, n.ahead = 5, nc = 1)
plot(x3)
# backtesting using 20 day-ahead forecasts and portfolio
x4 <- backtest(x1, window_length = 6000, portfolio_weights = c(0.5,0.5), n.ahead = 20, nc = 1)
plot(x4)</pre>
```

**BEKKs** 

BEKKs: Volatility modelling

#### **Description**

This package implements estimation, simulation and forecasting techniques for conditional volatility modelling using the BEKK model. The full BEKK(1,1,1) model of Engle and Kroner (1995)

$$H_t = CC' + A'r_{t-1}r'_{t-1}A + G'H_{t-1}G,$$

the asymmetric extensions of Kroner and Ng (1998) and Grier et. al. (2004)

$$H_t = CC' + A'r_{t-1}r'_{t-1}A + B'\gamma_{t-1}\gamma'_{t-1}B + G'H_{t-1}G$$

with

$$\gamma_t = r_t I \left( r_t < 0 \right)$$

are implemented. Moreover, the diagonal BEKK, where the parameter matrices A, B and G are reduced to diagonal matrices and the scalar BEKK model of Ding and Engle (2001)

$$H_t = CC' + ar_{t-1}r'_{t-1} + gH_{t-1},$$

where a and g are scalar parameters and are implemented to allow faster but less flexible estimation in higher dimensions.

#### **Details**

The main functions are:

bekk\_spec Specifies the model type to be estimated.

bekk\_fit Estimates a BEKK(1,1,1) model of a given series and specification object bekk\_spec.

•

4 BEKKs

simulate Simulates a BEKK(1,1,1) process using either a bekk\_fit or bekk\_spec object.

•

predict Forecasts conditional volatility using a bekk\_fit object.

•

VaR Estimates (portfolio) Value-at-Risk using a fitted BEKK(1,1,1) model.

•

backtest Backtesting estimated (portfolio) value-at-risks of a fitted BEKK(1,1,1) model.

•

virf Calculates volatility impulse response functions for fitted symmetric BEKK(1,1,1) models.

•

bekk\_fit 5

| bekk_fit Estimating multivariate BEKK-type volatility models |  |
|--|--|
|--|--|

#### **Description**

Method for fitting a variety of N-dimensional BEKK models.

#### Usage

```
bekk_fit(spec, data, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-09)
```

#### **Arguments**

An object of class "bekkSpec" from function bekk\_spec.

A multivariate data object. Can be a numeric matrix or ts/xts/zoo object.

QML\_t\_ratios

Logical. If QML\_t\_ratios = 'TRUE', the t-ratios of the BEKK parameter matrices are exactly calculated via second order derivatives.

Maximum number of BHHH algorithm iterations.

Crit

Determines the precision of the BHHH algorithm.

#### **Details**

The BEKK optimization routine is based on the Berndt–Hall–Hausman (BHHH) algorithm and is inspired by the study of Hafner and Herwartz (2008). The authors provide analytical formulas for the score and Hessian of several MGARCH models in a QML framework and show that analytical derivations significantly outperform numerical methods.

## Value

Returns a S3 class "bekkFit" object containing the estimated parameters, t-values, standard errors and volatility process of the model defined by the BEKK\_spec object.

#### References

Hafner and Herwartz (2008). Analytical quasi maximum likelihood inference in multivariate volatility models. Metrika, 67, 219-239.

#### **Examples**

```
data(StocksBonds)
# Fitting a symmetric BEKK model
obj_spec <- bekk_spec()
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
summary(x1)
plot(x1)
# Fitting an asymmetric BEKK model
obj_spec <- bekk_spec(model = list(type = "bekk", asymmetric = TRUE))</pre>
```

6 bekk\_spec

```
x1 <- bekk_fit(obj_spec, StocksBonds)
summary(x1)

plot(x1)

# Fitting a symmetric diagonal BEKK model
obj_spec <- bekk_spec(model = list(type = "dbekk", asymmetric = FALSE))
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
summary(x1)

plot(x1)

# Fitting a symmetric scalar BEKK model
obj_spec <- bekk_spec(model = list(type = "sbekk", asymmetric = FALSE))
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
summary(x1)

plot(x1)</pre>
```

bekk\_spec

BEKK specification method

## Description

Method for creating a N-dimensional BEKK model specification object prior to fitting and/or simulating.

## Usage

```
bekk_spec(
  model = list(type = "bekk", asymmetric = FALSE),
  init_values = NULL,
  signs = NULL,
  N = NULL
)
```

#### **Arguments**

model

A list containing the model type specification: Either "bekk" "dbekk" or "sbekk". Moreover it can be specified whether the model should be estimated allowing for asymmetric volatility structure.

init\_values

initial values for bekk\_fit during BHHH algorithm. It can be either a numerical vector of suitable dimension, 'NULL' (default) to use a simple grid search algorithm, or a character vector i.e. "random" to use a random starting value generator (set a seed in advance for reproducible results), or "simple" for relying on a simple initial values generator based on typical values for BEKK parameter found in the literature. If the object from this function is passed to simulate, "init\_values" are used as parameters for data generating process.

GoldStocksBonds 7

signs An N-dimensional vector consisting of "1" or "-1" to indicate the asymmetric

effects to be considered. Setting the i-th element of the vector to "1" or "-1" means that the model takes into account additional volatility if the returns of the i-th column in the data matrix are either positive or negative. If "asymmetric = TRUE", the default is set to "rep(-1, N)" i.e. it is assumed that excess volatility

occurs for all series if the returns are negative.

N Integer specifying the dimension of the BEKK model. Only relevant when this

object of class "bekkSpec"" is used for simulating BEKK processes by applying

it to simulate.

#### Value

Returns a S3 class "bekkSpec" object containing the specifications of the model to be estimated.

#### **Examples**

```
data(StocksBonds)
# Fitting a symmetric BEKK model using default starting values
# - i.e. fixed values
obj_spec_fixed <- bekk_spec(init_values = NULL)</pre>
x1 <- bekk_fit(obj_spec_fixed, StocksBonds, QML_t_ratios = FALSE,</pre>
max_iter = 50, crit = 1e-9)
# Fitting a symmetric BEKK model using initial values originating from a
# random grid search algorithm
obj_spec_random <- bekk_spec(init_values = "random")</pre>
x2 <- bekk_fit(obj_spec_random, StocksBonds, QML_t_ratios = FALSE,</pre>
max_iter = 50, crit = 1e-9)
summary(x1)
summary(x2)
plot(x1)
plot(x2)
# Fitting an asymmetric BEKK model with default starting values
obj_spec_fix <- bekk_spec(model = list(type = "bekk", asymmetric = TRUE),</pre>
init_values = NULL)
x1 <- bekk_fit(obj_spec_fix, StocksBonds)</pre>
obj_spec_random <- bekk_spec(model = list(type = "bekk", asymmetric = TRUE),</pre>
init_values = "random")
x2 <- bekk_fit(obj_spec_random, StocksBonds)</pre>
summary(x1)
summary(x2)
```

 ${\tt GoldStocksBonds}$ 

Gold stock and Bond returns

#### **Description**

Trivariate data set consisting of daily gold, S&P 500 and U.S. Treasury Bond Future returns from October 1991 to October 2021.

8 portmanteau.test

#### Usage

```
data("GoldStocksBonds")
```

#### **Format**

A time series matrix of class mts 7346 observations on the following 3 variables.

Gold a numeric vector

S&P 500 a numeric vector

US Treasury Bond Future a numeric vector

#### Source

Yahoo Finance.

#### **Examples**

```
data(GoldStocksBonds)
## maybe str(GoldStocksBonds) ; plot(GoldStocksBonds) ...
```

portmanteau.test

Performing a Portmanteau test checking for remaining correlation in the empirical co-variances of the estimated BEKK residuals.

#### **Description**

Method for a Portmanteau test of the null hypothesis of no remaining correlation in the co-variances of the estimated BEKK residuals.

#### Usage

```
portmanteau.test(x, lags = 5)
```

#### **Arguments**

x An object of class "bekkFit" from function bekk\_fit.

lags An integer defining the lag length.

## **Details**

Here, the multivariate Portmanteau test of Hosking (1980) is implemented.

#### Value

Returns an Object of class "htest" containing the p-value and test statistic.

#### References

J. R. M. Hosking (1980). The Multivariate Portmanteau Statistic, Journal of the American Statistical Association, 75:371, 602-608.

predict 9

predict

Forecasting conditional volatilities with BEKK models

#### **Description**

Method for predicting a N-dimensional BEKK covariances.

#### Usage

```
## S3 method for class 'bekk'
predict(object, n.ahead = 1, ci = 0.95, ...)
## S3 method for class 'bekka'
predict(object, n.ahead = 1, ci = 0.95, ...)
## S3 method for class 'dbekk'
predict(object, n.ahead = 1, ci = 0.95, ...)
## S3 method for class 'dbekka'
predict(object, n.ahead = 1, ci = 0.95, ...)
## S3 method for class 'sbekk'
predict(object, n.ahead = 1, ci = 0.95, ...)
## S3 method for class 'sbekka'
predict(object, n.ahead = 1, ci = 0.95, ...)
```

#### **Arguments**

| object  | A fitted bekk model of class "bekkFit" from the bekk_fit function  |
|---------|--|
| n.ahead | Number of periods to forecast conditional volatility. Default is a one-period ahead forecast.  |
| ci      | Floating point in [0,1] defining the niveau for confidence bands of the conditional volatility forecast. Default is 95 per cent niveau confidence bands. |
|         | Further parameters to be passed on to the function.  |

#### Value

Returns a S3 class "bekkForecast" object containing the conditional volatility forecasts and respective confindence bands.

## **Examples**

```
#'
data(StocksBonds)
obj_spec <- bekk_spec()
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
x2 <- predict(x1, n.ahead = 1)</pre>
```

10 simulate

print.bekkFit

bekkFit method

#### **Description**

Generic 'bekkFit' methods. More details on 'bekkFit' are described in bekk\_fit

## Usage

```
## S3 method for class 'bekkFit'
print(x, ...)
## S3 method for class 'bekkFit'
residuals(object, ...)
## S3 method for class 'bekkFit'
logLik(object, ..., k = 2)
```

#### **Arguments**

An object of class "bekkFit" from function bekk\_fit.
 Further arguments to be passed to and from other methods.
 An object of class "bekkFit" from function bekk\_fit.
 Numeric value, the penalty per parameter for AIC to be used; the default k = 2 is the classical AIC.

## **Examples**

```
data(StocksBonds)
# Fitting a symmetric BEKK model
obj_spec <- bekk_spec()
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
logLik(x1)</pre>
```

simulate

Simulating BEKK models

## **Description**

Method for simulating a N-dimensional BEKK model.

StocksBonds 11

#### Usage

```
## S3 method for class 'bekk'
simulate(object, nsim, ...)
## S3 method for class 'bekka'
simulate(object, ..., nsim)
## S3 method for class 'dbekk'
simulate(object, ..., nsim)
## S3 method for class 'dbekka'
simulate(object, ..., nsim)
## S3 method for class 'sbekk'
simulate(object, ..., nsim)
## S3 method for class 'sbekk'
simulate(object, ..., nsim)
```

#### **Arguments**

object A spec object of class "bekkSpec" from the function bekk\_spec or a fitted bekk model of class "bekkFit" from the bekk\_fit function

nsim Number of observations of the simulated sample

... Further parameters to be passed on to the function.

#### Value

Returns a simulated time series S3 class object using the parameters of passed "bekkSpec" or "bekkFit".

#### **Examples**

```
# simulate a BEKK with estimated parameter
obj_spec <- bekk_spec()
x1 <- bekk_fit(obj_spec, StocksBonds)

x2 <- simulate(x1, nsim = 3000)
plot(x2)</pre>
```

StocksBonds

Daily stock and Bond returns

#### **Description**

Bivariate data set consisting of daily S&P 500 bond and MSCI World returns from December 1995 to December 2019.

12 VaR

#### Usage

```
data("StocksBonds")
```

#### **Format**

A time series matrix of class mts with 6073 observations on the following 2 variables.

```
S&P 500 Bonds a numeric vector MSCI World a numeric vector
```

#### Source

Yahoo Finance.

#### **Examples**

```
data(StocksBonds)
## maybe str(StocksBonds) ; plot(StocksBonds) ...
```

VaR

Calculating Value-at-Risk (VaR)

#### **Description**

Method for calculating VaR from estimated covariance processes (bekk\_fit) or predicted covariances (predict).

## Usage

```
VaR(x, p = 0.99, portfolio_weights = NULL, distribution = "empirical")
```

#### Arguments

x An object of class "bekkFit" from the function bekk\_fit or an object of class "bekkForecast" from the function predict.

p A numerical value that determines the confidence level. The default value is set at 0.99 in accordance with the Basel Regulation.

portfolio\_weights

A vector determining the portfolio weights to calculate the portfolio VaR. If set to "NULL", the univariate VaR for each series are calculated.

distribution A character string determining the assumed distribution of the residuals. Im-

plemented are "normal", "empirical" and "t". The default is using the empirical

distribution of the residuals.

#### Value

Returns a S3 class "var" object containing the VaR forecast and respective confidence bands.

virf 13

#### **Examples**

```
data(StocksBonds)
obj_spec <- bekk_spec()
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
# single VaRs of series
x2 <- VaR(x1, distribution="normal")
plot(x2)
# VaR of equally-weighted portfolio
portfolio_weights <- c(0.5, 0.5)
x3 <- VaR(x1, portfolio_weights = portfolio_weights)
plot(x3)
# VaR of traditional 30/70 weighted bond and stock portfolio
portfolio_weights <- c(0.3, 0.7)
x4 <- VaR(x1, portfolio_weights = portfolio_weights)
plot(x4)</pre>
```

virf

Estimating multivariate volatility impulse response functions (VIRF) for BEKK models

## Description

Method for estimating VIRFs of N-dimensional BEKK models. Currently, only VIRFs for symmetric BEKK models are implemented.

## Usage

```
virf(
    x,
    time = 1,
    q = 0.05,
    index_series = 1,
    n.ahead = 10,
    ci = 0.9,
    time_shock = FALSE
)
```

#### **Arguments**

x An object of class "bekkfit" from function bekk\_fit.

time Time instance to calculate VIRFs for.

q A number specifying the quantile to be considered for a shock on which basis

the VIRFs are generated.

index\_series An integer defining the number of series for which a shock is assumed.

14 virf

n. ahead An integer defining the number periods for which the VIRFs are generated.

ci A number defining the confidence level for the confidence bands.

time\_shock Boolean indicating if the estimated residuals at date specified by "time" shall be

used as a shock.

#### Value

Returns an object of class "virf".

#### References

## **Examples**

```
data(StocksBonds)
obj_spec <- bekk_spec()
x1 <- bekk_fit(obj_spec, StocksBonds, QML_t_ratios = FALSE, max_iter = 50, crit = 1e-9)
# 250 day ahead VIRFs and 90% CI for a Shock in the 1% quantile of Bonds (i.e. series=2)
# shock is supposed to occur at day 500
x2 <- virf(x1, time = 500, q = 0.01, index_series=2, n.ahead = 500, ci = 0.90)
plot(x2)</pre>
